The present invention relates generally to the power and consumption management of integrated circuits, and more particularly, to a method and apparatus for automatically switching power supplies to a primary component of an integrated circuit when a secondary component enters or exits a powerdown mode. Integrated circuits are generally constructed of various active and/or passive components, such as inductors, transistors, resistors and capacitors, which are configured on a semiconductor substrate. As known in the art, these components are necessary for processing or performing certain functionalities of the integrated circuit. However, many of these components may be unnecessary for the functionalities of the integrated circuit. Generally, a power supply is used to provide power (or current) to the integrated circuit. The power supply is controlled so that the voltage of the power supply tracks a specified voltage. For example, a power supply can be controlled to provide voltage to a first (e.g., primary) power supply terminal of a first power supply such that the voltage at the first power supply terminal tracks an exact voltage. Similarly, a second power supply terminal of a second power supply can be controlled to provide a voltage to the second power supply terminal such that the voltage at the second power supply terminal tracks a second specified voltage. Typically, the first power supply terminal is supplied with power through a primary component such as a resistor or an inductor. However, in some instances, the first power supply terminal may be supplied with power from 82138339de
